Greatest Common Divisor (definition)

$\gcd(a, b)$ returns the greatest common divisor of integers a and b . There are efficient algorithms for finding the gcd, i.e. Euclidean algorithm.

Cryptography

Greatest Common Divisor (example)

$\gcd(12, 20) = 4$, since the divisors of 12 are (1, 2, 3, 4, 6, 12) and the divisors of 20 are (1, 2, 4, 5, 10, 20).

Relatively Prime (definition)

Two integers, a and b , are relatively prime if $\gcd(a, b) = 1$.

Relatively Prime (example)

$\gcd(7, 12) = 1$, since the divisors of 7 are (1, 7) and the divisors of 12 are (1, 2, 3, 4, 6, 12). Therefore 7 and 12 are relatively prime to each other.

Prime Number (definition)

An integer $p > 1$ is a *prime number* if and only if its only divisors are $+1$, -1 , $+p$ and $-p$.

Prime Number (example)

The divisors of 13 are (1, 13), that is, 1 and itself. Therefore 13 is a prime number. The divisors of 15 are (1, 3, 5, 15). Since the divisors include numbers other than 1 and itself, 15 is not prime.

Prime Factors (definition)

Any integer $a > 1$ can be factored as:

$$a = p_1^{a_1} \times p_2^{a_2} \times \cdots \times p_t^{a_t}$$

where $p_1 < p_2 < \cdots < p_t$ are prime numbers and where each a_i is a positive integer

Prime Factors (example)

The following are examples of integers expressed as prime factors:

$$13 = 13^1$$

$$15 = 3^1 \times 5^1$$

$$24 = 2^3 \times 3^1$$

$$50 = 2^1 \times 5^2$$

$$560 = 2^4 \times 5^1 \times 7^1$$

Prime Factorization Problem (definition)

There are no known efficient, non-quantum algorithms that can find the prime factors of a sufficiently large number.

Prime Factorization Problem (example)

RSA Challenge involved researchers attempting to factor large numbers. Largest number measured in number of bits or decimal digits. Some records held over time are:

1991: 330 bits or 100 digits

2005: 640 bits or 193 digits

2009: 768 bits or 232 digits

Equivalent of 2000 years on single core 2.2 GHz computer to factor 768 bit

Current algorithms such as RSA rely on numbers of 1024, 2048 and even 4096 bits in length

Euler's Totient Function (definition)

Euler's totient function, $\phi(n)$, is the number of positive integers less than n and relatively prime to n . Also written as $\varphi(n)$ or $\text{Tot}(n)$.

Properties of Euler's Totient (definition)

Several useful properties of Euler's totient are:

$$\phi(1) = 1$$

$$\text{For prime } p, \phi(p) = p - 1$$

$$\text{For primes } p \text{ and } q, \phi(pq) = \phi(p) \times \phi(q) = (p - 1) \times (q - 1)$$

Euler's Totient Function (example)

The integers relatively prime to 10, and less than 10, are: 1, 3, 7, 9. There are 4 such numbers. Therefore $\phi(10) = 4$.

The integers relatively prime to 11, and less than 11, are: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. There are 10 such numbers. Therefore $\phi(11) = 10$. The property could also be used since 11 is prime.

Since 7 is prime, $\phi(7) = 6$.

Since $77 = 7 \times 11$, then $\phi(77) = \phi(7 \times 11) = 6 \times 10 = 60$.

Modular arithmetic simple (definition)

Modular arithmetic is similar to normal arithmetic (addition, subtraction, multiplication, division) but the answers “wrap around”.

mod operator (definition)

If a is an integer and n is a positive integer, then $a \bmod n$ is defined as the remainder when a is divided by n . n is called the *modulus*.

mod operator (example)

The following are several examples of mod:

$$3 \bmod 7 = 3, \text{ since } 0 \times 7 + 3 = 3$$

$$9 \bmod 7 = 2, \text{ since } 1 \times 7 + 2 = 9$$

$$10 \bmod 7 = 3, \text{ since } 1 \times 7 + 3 = 10$$

$$(-3) \bmod 7 = 4, \text{ since } (-1) \times 7 + 4 = -3$$

Congruent modulo (definition)

Two integers a and b are *congruent modulo n* if $(a \bmod n) = (b \bmod n)$. The congruence relation is written as:

$$a \equiv b \pmod{n}$$

When the modulus is known from the context, it may be written simply as $a \equiv b$.

Congruent modulo (example)

The following are examples of congruence:

$$3 \equiv 10 \pmod{7}$$

$$14 \equiv 4 \pmod{10}$$

$$3 \equiv 11 \pmod{8}$$

Modular arithmetic (definition)

Modular arithmetic with modulus n performs arithmetic operations within the confines of set $Z_n = \{0, 1, 2, \dots, (n - 1)\}$.

mod in Z_7 (example)

Consider the set:

$$Z_7 = \{0, 1, 2, 3, 4, 5, 6\}$$

All modular arithmetic operations in mod 7 return answers in Z_7 .

Modular Arithmetic

- ▶ If a is an integer and n is a positive integer, we define $a \bmod n$ to be the remainder when a is divided by n
- ▶ n is called the *modulus*
- ▶ Two integers a and b are *congruent modulo n* if $(a \bmod n) = (b \bmod n)$, which is written as

$$a \equiv b \pmod{n}$$

- ▶ $(\bmod n)$ operator maps all integers into the set of integers $Z_n = \{0, 1, \dots, (n - 1)\}$
- ▶ *Modular arithmetic* performs arithmetic operations within confines of set Z_n

Modular Addition (definition)

Addition in mod n is performed as normal addition, with the answer then mod by n .

Modular Addition (example)

The following are several examples of modular addition:

$$2 + 3 \pmod{7} = 5 \pmod{7} = 5 \pmod{7} = 5 \pmod{7}$$

$$2 + 6 \pmod{7} = 8 \pmod{7} = 8 \pmod{7} = 1 \pmod{7}$$

$$6 + 6 \pmod{7} = 12 \pmod{7} = 12 \pmod{7} = 5 \pmod{7}$$

$$3 + 4 \pmod{7} = 7 \pmod{7} = 7 \pmod{7} = 0 \pmod{7}$$

Additive Inverse (definition)

a is the *additive inverse* of b in mod n , if $a + b \equiv 0 \pmod{n}$.

For brevity, $AI(a)$ may be used to indicate the additive inverse of a . One property is that all integers have an additive inverse.

Additive Inverse (example)

In mod 7:

$$AI(3) = 4, \text{ since } 3 + 4 \equiv 0 \pmod{7}$$

$$AI(6) = 1, \text{ since } 6 + 1 \equiv 0 \pmod{7}$$

In mod 12:

$$AI(3) = 9, \text{ since } 3 + 9 \equiv 0 \pmod{12}$$

Modular Subtraction (definition)

Subtraction in mod n is performed by addition of the additive inverse of the subtracted operand. This is effectively the same as normal subtraction, with the answer then mod by n .

Modular Subtraction (example)

For brevity, the modulus is sometimes omitted and $=$ is used in replace of \equiv . In mod 7:

$$6 - 3 = 6 + A1(3) = 6 + 4 = 10 = 3 \pmod{7}$$

$$6 - 1 = 6 + A1(1) = 6 + 6 = 12 = 5 \pmod{7}$$

$$1 - 3 = 1 + A1(3) = 1 + 4 = 5 \pmod{7}$$

While the first two examples obviously give answers as we expect from normal subtraction, the third does as well. $1 - 3 = -2$, and in mod 7, $-2 \equiv 5$ since $-1 \times 7 + 5 = (-2)$. Recall $Z_7 = \{0, 1, 2, 3, 4, 5, 6\}$.

Modular Multiplication (definition)

Number Theory

Modular multiplication is performed as normal multiplication, with the answer then mod by n .

Divisibility and Primes

Modular Arithmetic

Fermat's and Euler's Theorems

Discrete Logarithms

Computationally Hard Problems

Modular Multiplication (example)

In mod 7:

$$2 \times 3 = 6 \pmod{7}$$

$$2 \times 6 = 12 = 5 \pmod{7}$$

$$3 \times 4 = 12 = 5 \pmod{7}$$

Multiplicative Inverse (definition)

a is a multiplicative inverse of b in mod n if $a \times b \equiv 1 \pmod{n}$. For brevity, $\text{MI}(a)$ may be used to indicate the multiplicative inverse of a . a has a multiplicative inverse in $(\text{mod } n)$ if a is relatively prime to n .

Multiplicative Inverse in mod 7 (example)

2 and 7 are relatively prime, therefore 2 has a multiplicative inverse in mod 7.

$$2 \times 4 \pmod{7} = 1, \text{ therefore } MI(2) = 4 \text{ and } MI(4) = 2$$

3 and 7 are relatively prime, therefore 3 has a multiplicative inverse in mod 7.

$$3 \times 5 \pmod{7} = 1, \text{ therefore } MI(3) = 5 \text{ and } MI(5) = 3$$

$\phi(7) = 6$, meaning 1, 2, 3, 4, 5 and 6 are relatively prime with 7, and therefore all of those numbers have a MI in mod 7.

Multiplicative Inverse in mod 8 (example)

3 and 8 are relatively prime, therefore 3 has a multiplicative inverse in mod 8.

$$3 \times 3 \pmod{8} = 1, \text{ therefore } MI(3) = 3$$

4 and 8 are NOT relatively prime, therefore 4 does not have a multiplicative inverse in mod 8. $\phi(8) = 4$, and therefore only 4 numbers (1, 3, 5, 7) have a MI in mod 8.

Modular Division (definition)

Division in mod n is performed as modular multiplication of the multiplicative inverse of 2nd operand. Modular division is only possible when the 2nd operand has a multiplicative inverse, otherwise the operation is undefined.

Modular Division (example)

In mod 7:

$$5 \div 2 = 5 \times MI(2) = 5 \times 4 = 20 \equiv 6$$

In mod 8:

$$7 \div 3 = 7 \times MI(3) = 7 \times 3 = 21 \equiv 5$$

$7 \div 4$ is undefined, since 4 does not have a multiplicative inverse in mod 8.

Properties of Modular Arithmetic (definition)

$$(a \bmod n) \bmod n = a \bmod n$$

$$[(a \bmod n) + (b \bmod n)] \bmod n = (a + b) \bmod n$$

$$[(a \bmod n) - (b \bmod n)] \bmod n = (a - b) \bmod n$$

$$[(a \bmod n) \times (b \bmod n)] \bmod n = (a \times b) \bmod n$$

Commutative, associative and distributive laws similar to normal arithmetic also hold.

Fermat's Theorem 1 (definition)

If p is prime and a is a positive integer not divisible by p , then:

$$a^{p-1} \equiv 1 \pmod{p}$$

Fermat's Theorem 2 (definition)

If p is prime and a is a positive integer, then:

$$a^p \equiv a \pmod{p}$$

There are two forms of Fermat's theorem—use whichever form is most convenient.

Euler's Theorem 1 (definition)

For every a and n that are relatively prime:

$$a^{\phi(n)} \equiv 1 \pmod{n}$$

Euler's Theorem 2 (definition)

For positive integers a and n :

$$a^{\phi(n)+1} \equiv a \pmod{n}$$

Note that there are two forms of Euler's theorem—use the most relevant form.

Euler's theorem (example)

Show that $37^{40} \bmod 41 = 1$. Since $n = 41$, which is prime, then $\phi(41) = 40$. As 37 is also prime, 37 and 41 are relatively prime. Therefore Euler's Theorem form 1 holds.

Euler's theorem (example)

What is $13794^{4621} \pmod{4757}$? Factoring 4757 into primes gives 67×71 .

Therefore $\phi(4757) = \phi(67) \times \phi(71) = 66 \times 70 = 4620$. Therefore, this follows Euler's Theorem form 2, giving an answer of 13794.

Modular Exponentiation (definition)

As exponentiation is just repeated multiplication, modular exponentiation is performed as normal exponentiation with the answer mod by n .

Modular Exponentiation (example)

$$2^3 \bmod 7 = 8 \bmod 7 = 1$$

$$3^4 \bmod 7 = 81 \bmod 7 = 4$$

$$3^6 \bmod 8 = 729 \bmod 8 = 1$$

Normal Logarithm (definition)

If $b = a^i$, then:

$$i = \log_a(b)$$

read as “the log in base a of b is index (or exponent) i ”.

The above definition is for normal arithmetic, not for modular arithmetic. Logarithm in normal arithmetic is the inverse operation of exponentiation. In modular arithmetic, modular logarithm is more commonly called *discrete logarithm*. Note we replace n with p —the reason will become apparent shortly.

Discrete Logarithm (definition)

If $b = a^i \pmod{p}$, then:

$$i = \text{dlog}_{a,p}(b)$$

A unique exponent i can be found if a is a *primitive root* of the prime p .

Primitive Root (definition)

If a is a primitive root of prime p then $a_1, a_2, a_3, \dots, a_{p-1}$ are distinct in mod p .

The integers with a primitive root are: $2, 4, p^\alpha, 2p^\alpha$ where p is any odd prime and α is a positive integer.

Primitive Root (example)

Consider the prime $p = 7$:

$$a = 1 : 1^2 \bmod 7 = 1, 1^3 \bmod 7 = 1, \dots (\text{not distinct})$$

$$a = 2 : 2^2 \bmod 7 = 4, 2^3 \bmod 7 = 1, 2^4 \bmod 7 = 2, 2^5 \bmod 7 = 4, \dots (\text{not distinct})$$

$$a = 3 : 3^2 \bmod 7 = 2, 3^3 \bmod 7 = 6, 3^4 \bmod 7 = 4, 3^5 \bmod 7 = 5, 3^6 \bmod 7 = 1 (\text{distinct})$$

Therefore 3 is a primitive root of 7 (but 1 and 2 are not).

Computationally Hard Problems

Hard Problem: Integer Factorisation (definition)

If p and q are unknown primes, given $n = pq$, find p and q .

Also known as prime factorisation. While someone that knows p and q can easily calculate n , if an attacker knows only n they cannot find p and q .

Hard Problem: Euler's Totient (definition)

Given composite n , find $\phi(n)$.

While it is easy to calculate Euler's totient of a prime, or of the multiplication of two primes if those primes are known, an attacker cannot calculate Euler's totient of sufficiently large non-prime number. Solving Euler's totient of n , where $n = pq$, is considered to be harder than integer factorisation.

Hard Problem: Discrete Logarithms (definition)

Given b , a , and p , find i such that $i = \text{dlog}_{a,p}(b)$.

While modular exponentiation is relatively easy, such as calculating $b = a^i \bmod p$, the inverse operation of discrete logarithms is computationally hard. The complexity is considered comparable to that of integer factorisation.

When studying RSA and Diffie-Hellman, you will see how these hard problems in number theory are used to secure ciphers.
