## Modular Arithmetic

- Use non-negative integers less than $n$
- Perform normal addition/multiplication
- Replace answer with its remainder when divided by n
- Result is called: "modulo n" or "mod n"
- Example (mod 10):
- Addition: $5+5=0$
$3+9=2$
$2+2=4$
- Multiply: $5 \times 5=5$
$3 \times 9=7$
$2 \times 2=4$
- Exponent: $5^{5}=5$
$3^{9}=3$
$2^{2}=4$
- Subtraction: add $-x$; -x is additive inverse of x
- Division: multiplicative inverse
- There is only an inverse for some values - found by Euclids algorithm
- All multiplicative inverse are relatively prime to modulo (e.g. 10)
- Inverse exponentiation
- There is only an inverse for some values

## Modular Addition (mod 10)

## Number Theory

- Prime Numbers
- A positive integer is a prime number if and only if it is evenly divisible by exactly two positive integers (itself and 1)
- Any integer can be factored only by primes
- Two numbers are relatively prime if they have no prime factors in common
- Or their greatest common divisor is 1
- Fermat's Theorem
- If $p$ is prime and $a$ is a positive integer not divisible by $p$, then

$$
a^{p-1} \equiv 1(\bmod p)
$$

- Or alternatively: if $p$ is prime and $a$ is a positive integer then

$$
a^{p} \equiv a(\bmod p)
$$

## Number Theory

- Relatively Prime
- Two numbers that don't share any common factors
- 7 is relatively prime to 10 - both have common divisor of 1
- 9 is relatively prime to 10 - both have common divisor of 1
- 6 is NOT relatively prime to 10 - both have common divisor of 2 and 1
- Euler's Totient Function: $\phi(n)$
- Number of integers less than $n$ and relatively prime to $n$
- For a prime, $p, \phi(p)=p-1$
- For two primes, $p$ and $q, \phi(p \times q)=\phi(p) \times \phi(q)$
- Euler's Theorem:
- For every $a$ and $n$ that are relatively prime: $a^{\phi(n)} \equiv 1(\bmod n)$
- Alternatively, $a^{\phi(n)+1} \equiv a(\bmod n)$

## Testing for Primality

- Many cryptographic algorithms need very large prime numbers
- How do we find very large prime numbers?
- There is no simple, efficient algorithm known
- Miller-Rabin Algorithm
- Does not give definite result
- Returns "composite" or "inconclusive"
- Running the test many times can increase confidence that number is prime
- Efficient algorithm
- There are some deterministic algorithms, but not as efficient
