Attacks on Communications across Network

- 1. Disclosure: encryption
- 2. Traffic analysis: encryption
- 3. Masquerade: message authentication
- 4. Content modification: message authentication
- 5. Sequence modification: message authentication
- 6. Timing modification: message authentication
- 7. Source repudiation: digital signatures
- 8. Destination repudiation: digital signatures

Functions

Auth. with MAC

Security

Algorithm

Authentication

- Receiver wants to verify:
 - 1. Contents of the message have not been modified (*data authentication*)
 - 2. Source of message is who they claim to be (*source authentication*)
- Different approaches available:
 - Symmetric Key Encryption
 - Message Authentication Codes (MACs)
 - Hash Functions
 - Public Key Encryption (i.e. Digital Signatures)

- ► Confidentiality: only B (and A) can recover plaintext
- Source Authentication: A is only other user with key;
 must have come from A
- Data Authentication: successfully decrypted; data has not been modified
- Assumption: decryptor can recognise correct plaintext

Auth. with MA

Securit

Algorithn

Recognising Correct Plaintext

Example 1

B receives ciphertext (supposedly from A, using shared secret key K):

DPNFCTEJLYONCJAEZRCLASJTDQFY

B decrypts with key K to obtain plaintext:

SECURITYANDCRYPTOGRAPHYISFUN

- ▶ Was the plaintext encrypted with key K (and hence sent by A)?
- ▶ Is the ciphertext received the same as the ciphertext sent by *A*?

Security

Algorithm

Recognising Correct Plaintext

Example 1

- ► Assume the message is English
- ► Plaintext had expected structure; assume the plaintext is correct
 - Sent by A and has not been modified

Example 2

- Assume the message is English
- Plaintext had no structure in expected language; assume plaintext is incorrect
 - ▶ Either not sent by A or modified

Example 3

- ▶ Binary data, e.g. image, compressed file
- Cannot know whether correct or incorrect

Functions

Auth. with MAC

Securit

Algorithm:

Recognising Correct Plaintext

- Valid plaintexts should be small subset of all possible messages
 - ► E.g. 26ⁿ possible messages of length *n*; only small subset are valid English phrases
- ► Plaintext messages have structure
- ▶ BUT automatically detecting structure can be difficult
- ▶ Add structure to make it easier, e.g.
 - ► Error detecting code or Frame Check Sequence
 - Packet header

Security

Algorithms

Authentication with Message Authentication Codes

Append small, fixed-size block of data to message: cryptographic checksum or MAC

$$T = \mathrm{MAC}(K, M)$$

M = input message

MAC = MAC function

K =shared secret key of k bits

T =message authentication code (or tag) of n bits

- ▶ MAC function also called *keyed hash function*
- MAC function similar to encryption, but does not need to be reversible
 - Easier to design stronger MAC functions than encryption functions

Requirement of MACs

Objective of Attacker

- ► Assume MAC function is known, key *K* is not
- ► For valid MAC code for given message *x*

Requirement of MAC Function

Computation Resistance: given one or more text-MAC pairs $[x_i, MAC(K, x_i)]$, computationally infeasible to compute any text-MAC pair [x, MAC(K, x)] for new input $x \neq x_i$

Security of MACs

Function

Auth. wi

Auth. with MA

Security

Algorithm

Brute Force Attack on Key

- ▶ Attacker knows $[x_1, T_1]$ where $T_1 = MAC(K, x_1)$
- ▶ Key size of k bits: brute force on key, 2^k
- ▶ But . . . many tags match T_1
- ▶ For keys that produce tag T_1 , try again with $[x_2, T_2]$
- ▶ Effort to find *K* is approximately 2^{*k*}

Brute Force Attack on MAC value

- For x_m , find T_m without knowing K
- Similar effort required as one-way/weak collision resistant property for hash functions
- For *n* bit MAC value length, effort is 2^n

Effort to break MAC: $\min(2^k, 2^n)$

Security of MACs

Functions

Auth. with

Auth. with MAG

Security

Algorithms

Cryptanalysis

- Many different MAC algorithms; attacks specific to algorithms
- ► MAC algorithms generally considered secure

Algorithms

MACs Based on Block Ciphers

- Data Authentication Algorithm (DAA): based on DES; considered insecure
- ▶ Cipher-Based Message Authentication Code (CMAC): mode of operation used with Triple-DES and AES
- ► OMAC, PMAC, UMAC, VMAC, ...

Algorithms

HMAC

- MAC function derived from cryptographic hash functions
 - ► MD5/SHA are fast in software (compared to block ciphers)
 - Libraries for hash functions widely available

$$\mathrm{HMAC}(K,M) = \mathrm{H}((K \oplus \mathrm{opad})||\mathrm{H}((K \oplus \mathit{ipad})||M))$$

where ipad = 00110110 repeated, opad = 01011100repeated

Security of HMAC depends on security of hash function used
