# **Encryption for Confidentiality**

- ► Aim: assure confidential information not made available to unauthorised individuals (data confidentiality)
- How: encrypt the original data; anyone can see the encrypted data, but only authorised individuals can decrypt to see the original data
- Used for both sending data across network and storing data on a computer system

### Model of Encryption for Confidentiality

### Terminology

Plaintext original message

Ciphertext encrypted or coded message

Encryption convert from plaintext to ciphertext (enciphering)

Decryption restore the plaintext from ciphertext (deciphering)

Key information used in cipher known only to sender/receiver

Cipher a particular algorithm (cryptographic system)

Cryptography study of algorithms used for encryption

Cryptanalysis study of techniques for decryption without knowledge of plaintext

Cryptology areas of cryptography and cryptanalysis

# Requirements and Assumptions

### Encrypt for Confidentiality

Requirements for secure use of symmetric encryption:

- 1. Strong encryption algorithm: Given the algorithm and ciphertext, an attacker cannot obtain key or plaintext
- 2. Sender/receiver know secret key (and keep it secret)

### Assumptions:

- Cipher is known
- Secure channel to distribute keys

# Characterising Cryptographic Systems

### Operations used for encryption:

Substitution replace one element in plaintext with another

Transposition re-arrange elements

Product systems multiple stages of substitutions and transpositions

### Number of keys used:

Symmetric sender/receiver use same key (single-key, secret-key, shared-key, conventional)

Public-key sender/receiver use different keys (asymmetric)

### Processing of plaintext:

Block cipher process one block of elements at a time

Stream cipher process input elements continuously

### Block Ciphers

- ► Encrypt block of plaintext at a time, typically 64 or 128 bits
- Slow algorithms/implementations
- Can re-use keys

### Stream Ciphers

- Encrypt 1 byte of plaintext at a time
- Encryption performed by XOR plaintext with keystream (created by pseudo-random number generator)
- Fast algorithms/implementations
- Cannot re-use keys

# Data Encryption Standard (DES)

- Designed by IBM and NSA; standardised by NIST in 1977 as FIPS-46
  - ▶ 1999: NIST recommended Triple-DES; DES only for legacy systems
  - 2005: FIPS-46 standard withdrawn
- Block size: 64 bits
- Key length: 56 bits (64 bits, but 8 are parity)
- ► Initial and final permutations, then 16 rounds, each involving permutations and substitutions
- Feistel structure
- lackbox Decryption is almost identical to encryption ightarrow single implementation for both algorithms
- ► Key size is insecure; algorithm considered secure
- Status: not recommended

### **DES Encryption Operations**

### Other Symmetric Encryption Algorithms

- ▶ Blowfish (Schneier, 1993): 64 bit blocks/32–448 bit keys; Feistel structure
- ► Twofish (Schneier et al, 1998): 128/128, 192, 256; Feistel structure
- Serpent (Anderson et al, 1998): 128/128, 192, 256;
   Substitution-permutation network
- ► Camellia (Mitsubishi/NTT, 2000): 128/128, 192, 256; Feistel structure
- ▶ IDEA (Lai and Massey, 1991): 64/128
- ► CAST-128 (Adams and Tavares, 1996): 64/40–128; Feistel structure
- ► CAST-256 (Adams and Tavares, 1998): 128/up to 256; Feistel structure
- ► RC5 (Rivest, 1994): 32, 64 or 128/up to 2040; Feistel-like structure
- ► RC6 (Rivest et al, 1998): 128/128, 192, 256; Feistel structure

### Assumptions: Symmetric Key Encryption

Encrypt for Confidentiality

Symmetric Key

Authenticatio

Public Ke

Key Managemen

Signature

Random Numbe

\_

- ▶ The same secret key, K, is used for encryption, E(), and decryption, D(). The secret is shared between two entities, i.e.  $K_{AB}$ .
- ▶ Encrypting plaintext, P, with a key, produces ciphertext C, e.g.  $C = E(K_{AB}, P)$ .
- Decrypting ciphertext with the correct key will produce the original plaintext. The decrypter will be able to recognise that the plaintext is correct (and therefore the key is correct). E.g.  $P = D(K_{AB}, C)$ .
- Decrypting ciphertext using the incorrect key will not produce the original plaintext. The decrypter will be able to recognise that the key is wrong, i.e. the decryption will produce unrecognisable output.

# Using Block Ciphers on Real Data

- ▶ Block ciphers typical operate on 64 or 128 bit blocks
- Modes of operation are used to apply ciphers on multiple blocks
  - Electronic Code Book (ECB), Cipher Block Chaining (CBC), Cipher Feedback Mode (CFB), Output Feedback Mode (OFB), Counter (CTR), XTS-AES
- ► Trade-offs: security, parallelism, error propagation
- Often require Initialisation Vector (IV)
- ► CFB, OFB and CTR can turn block cipher into stream cipher

### Authentication

- Receiver wants to verify:
  - 1. Contents of the message have not been modified (*data authentication*)
  - 2. Source of message is who they claim to be (*source authentication*)
- Different approaches available:
  - Symmetric Key Encryption
  - Message Authentication Codes
  - ► Hash Functions
  - Public Key Encryption (see Digital Signatures)

#### Cryptography

Summary

# Authentication using Symmetric Key Encryption

- Assumption: decryption using wrong key or modified ciphertext will produce unintelligible output
- Symmetric key encryption can provide: data authentication and source authentication (as well as confidentiality)

Credit: Figure 12.1(a) in Stallings, Cryptography and Network Security, 5th Ed., Pearson 2011

- ► However, typically authentication is performed separately to encryption for confidentiality
  - Avoid overhead of using encryption when not needed

Key Managemer

Signature

Random Numbe

Summa

# Authentication using Message Authentication Codes

Append small, fixed-size block of data to message: cryptographic checksum or MAC

$$\mathrm{MAC} = \mathrm{F}(K,M)$$

M = input message

F = MAC function

K =shared secret key of k bits

MAC =message authentication code (or tag) of n bits

- MAC function also called keyed hash function
- MAC function similar to encryption, but does not need to be reversible
  - Easier to design stronger MAC functions than encryption functions

Summary

## MAC Algorithms

- Data Authentication Algorithm (DAA): based on DES; considered insecure
- Cipher-Based Message Authentication Code (CMAC): mode of operation used with Triple-DES and AES
- ► OMAC, PMAC, UMAC, VMAC, ...
- HMAC: MAC function derived from cryptographic hash functions
  - MD5/SHA are fast in software (compared to block ciphers)
  - Libraries for hash functions widely available
  - Security of HMAC depends on security of hash function used

### **MAC Attacks**

Encrypt for Confidentiality

Symmetric Key

Authentication

Public Ke

Key Managemer

Signatures

Random Numbe

Summary

### Security Requirement

- Key is secret and difficult to find from pairs of (M, MAC)
- Given pairs of (M, MAC), difficult to find the MAC of another message

### Brute Force Attacks on MACs

- ▶ Option 1: Try all possible keys for one or more pairs of (MAC, M); effort  $\approx 2^k$
- ▶ Option 2: Try many values of M to find correct MAC; effort  $\approx 2^n$
- ▶ Effort to break MAC:  $\min(2^k, 2^n)$

# Birth of Public-Key Cryptosystems

- ▶ Beginning to 1960's: permutations and substitutions (Caesar, rotor machines, DES, ...)
- ▶ 1960's: NSA secretly discovered public-key cryptography
- ▶ 1970: first known (secret) report on public-key cryptography by CESG, UK
- ▶ 1976: Diffie and Hellman public introduction to public-key cryptography
  - Avoid reliance on third-parties for key distribution
  - Allow digital signatures
- ▶ 1978: Rivest, Shamir and Adlemen created RSA

Summar

# Principles of Public-Key Cryptosystems

- Symmetric algorithms used same secret key for encryption and decryption
- Asymmetric algorithms in public-key cryptography use one key for encryption and different but related key for decryption
- Characteristics of asymmetric algorithms:
  - Require: Computationally infeasible to determine decryption key given only algorithm and encryption key
  - ▶ Optional: Either of two related keys can be used for encryption, with other used for decryption

# Public and Private Keys

### Public Key

- ► For secrecy: used in encryption
- ► For authentication: used in decryption
- Available to anyone

### Private Key

- ► For secrecy: used in decryption
- ▶ For authentication: used in decryption
- Secret, known only by owner

### Public-Private Key Pair

▶ User A has pair of related keys, public and private:  $(PU_A, PR_A)$

Summary

# Applications of Public Key Cryptosystems

- Secrecy, encryption/decryption of messages
- ▶ Digital signature, *sign* message with private key
- ► Key exchange, share secret session keys

| Algorithm      | Encryption/Decryption | Digital Signature | Key Exchange |
|----------------|-----------------------|-------------------|--------------|
| RSA            | Yes                   | Yes               | Yes          |
| Elliptic Curve | Yes                   | Yes               | Yes          |
| Diffie-Hellman | No                    | No                | Yes          |
| DSS            | No                    | Yes               | No           |

Public Key

# Requirements of Public-Key Cryptography

- 1. Computationally easy for B to generate pair  $(PU_b, PR_b)$
- 2. Computationally easy for A, knowing  $PU_b$  and message M, to generate ciphertext:

$$C = E(PU_b, M)$$

3. Computationally easy for B to decrypt ciphertext using  $PR_h$ :

$$M = D(PR_b, C) = D[PR_b, E(PU_b, M)]$$

- 4. Computationally infeasible for attacker, knowing  $PU_h$ and C, to determine  $PR_h$
- 5. Computationally infeasible for attacker, knowing  $PU_h$ and C, to determine M
- 6. (Optional) Two keys can be applied in either order:

$$M = D[PU_b, E(PR_b, M)] = D[PR_b, E(PU_b, M)]$$

A .1 ...

Authenticatio

Public Key

Key Managemer

Signature

Random Number

Summa

6 requirements lead to need for trap-door one-way function

- Every function value has unique inverse
- ► Calculation of function is easy
- ► Calculation of inverse is infeasible, unless certain information is known

$$Y = f_k(X)$$
 easy, if  $k$  and  $Y$  are known  $X = f_k^{-1}(Y)$  easy, if  $k$  and  $Y$  are known  $X = f_k^{-1}(Y)$  infeasible, if  $Y$  is known but  $k$  is not

- ▶ What is easy? What is infeasible?
  - Computational complexity of algorithm gives an indication
  - Easy if can be solved in polynomial time as function of input

Symmetric Key

Authentication

Public Key

Signatures

Random Numbe

Summar

### Brute Force Attacks

- Use large key to avoid brute force attacks
- Public key algorithms less efficient with larger keys
- ► Public-key cryptography mainly used for key management and signatures

### Compute Private Key from Public Key

▶ No known feasible methods using standard computing

### Probable-Message Attack

- ▶ Encrypt all possible M' using  $PU_b$ —for the C' that matches C, attacker knows M
- ► Only feasible of *M* is short
- ► Solution for short messages: append random bits to make it longer

# Example Public-Key Algorithm: RSA

Encrypt for Confidentiality

Symmetric Key

Authenticatio

Public Key

Key Managemer

Signature

Random Numb

Summar

# Key Generation

- 1. Choose primes p and q, and calculate n = pq
- 2. Select e:  $gcd(\phi(n), e) = 1, 1 < e < \phi(n)$
- 3. Find  $d \equiv e^{-1} \pmod{\phi(n)}$

n and e are public; p, q and d are private

### Encryption

Encryption of plaintext M, where M < n:

$$C = M^e \mod n$$

### Decryption

Decryption of ciphertext *C*:

$$M = C^d \mod n$$

# Example Public-Key Algorithm: RSA

- Created by Ron Rivest, Adi Shamir and Len Adleman in 1978
- Security of RSA
  - 1. Brute force attack on *d*
  - 2. Factor *n* into its two prime factors
  - 3. Determine  $\phi(n)$  directly, without determining p or q
  - 4. Determine d directly, without determining  $\phi(n)$
- ► Factoring is considered the easiest. Some records by length of *n*:
  - ▶ 1991: 330 bits (100 digits)
  - ▶ 2003: 576 bits (174 digits)
  - 2005: 640 bits (193 digits)
  - ▶ 2009: 768 bit (232 digits), 10<sup>20</sup> operations, 2000 years on single core 2.2 GHz computer
- ▶ Typical length of *n*: 1024 bits, 2048 bits, 4096 bits

Summary

# Assumptions: Public Key Encryption

- ► There is a pair of keys, public (PU) and private (PR). One key from the pair is used for encryption, the other is used for decryption. Each entity has their own pair, e.g. (PUA, PRA).
- ▶ Encrypting a plaintext message, M, with a key, produces ciphertext C, e.g.  $C = E(PU_A, M)$ .
- Decrypting ciphertext with the correct key will produce the original plaintext. The decrypter will be able to recognise that the plaintext is correct (and therefore the key is correct). E.g.  $M = D(PR_A, C)$ .
- Decrypting ciphertext using the incorrect key will not produce the original plaintext. The decrypter will be able to recognise that the key is wrong, i.e. the decryption will produce unrecognisable output.

## Challenges

- ► How to share a secret key?
- ▶ How to obtain someone else's public key?
- ▶ When to change keys?

### Assumptions and Principles

- Many users wish to communicate securely across network
- Attacker can intercept any location in network
- Manual interactions between users are undesirable (e.g. physical exchange of keys)
- ▶ More times a key is used, greater chance for attacker to discover the key

# Exchanging Secret Keys

### Option 1: Manual Exchange of All Keys

- All users exchange secret keys with all other users manually (e.g. face-to-face)
- ► Inconvenient

### Option 2: Manual Exchange of Master Keys

- ► All users exchange master key with trusted, central entity (e.g. Key Distribution Centre)
- Session keys automatically exchanged between users via KDC
- Security and performance bottleneck at KDC

Random Numbe

Summar

# Exchanging Secret Keys

## Option 3: Public Key Cryptography to Exchange Secrets

- Use public-key cryptography to securely and automatically exchange secret keys
- Example 1: user A encrypts secret with user B's public key; sends to B
- ► Example 2: Diffie-Hellman secret key exchange

# Distributing Public Keys

- By design, public keys are made public
- Issue: how to ensure public key of A actually belongs to A (and not someone pretending to be A)
- Approaches for public key distribution
  - 1. Public announcement (web page, email, newspaper)
  - 2. Publish in electronic directory (which manually authenticates users)
  - 3. Public key authority:
    - Users manually publish key at authority, and gain authorities public key
    - Users automatically request other users public keys from authority
  - 4. Public key certificates
    - Users manually register with authority
    - Authority issues certificates to users: users public key signed by authority
    - Users automatically exchange certificates

Summar

# Key Hierarchy and Lifetimes

- Master keys used to securely exchange session keys
- Session keys used to securely exchange data
- ► Change session keys automatically and regularly
- Change master keys manually and seldom
- Session key lifetime:
  - Shorter lifetime is more secure; but increases overhead of exchanges
  - Connection-oriented protocols (e.g. TCP): new session key for each connection
  - Connection-less protocols (e.g. UDP/IP): change after fixed period or certain number of packets sent

## Digital Signatures

- ▶ Aim of a signature: prove to anyone that a message originated at (or is approved by) a particular user
- Symmetric key cryptography
  - ► Two users, A and B, share a secret key K
  - Receiver of message (user A) can verify that message came from the other user (B)
  - ▶ User C cannot prove that the message came from B (it may also have came from A)
- ► Public key cryptography can provide signature: only one user has the private key

Authentication

Public Key

Kev Managemer

Signatures

Random Number

Summar

## Signing

▶ User signs a message by encrypting with own private key

$$S = E(PR_A, M)$$

User attaches signature to message

### Verification

 User verifies a message by decrypting signature with signer's public key

$$M' = D(PU_A, S)$$

► User then compares received message *M* with decrypted *M*′; if identical, signature is verified

## Examples of Random Numbers in Cryptography

- Generate keys in public key algorithms
- ► Keystream in stream ciphers
- ► Generate session keys for symmetric ciphers
- Authentication and key distribution protocols to prevent replays

### Requirements of Sequence of Random Numbers

- ► Randomness, e.g. selecting large prime numbers for RSA involves selecting random numbers and checking that they are not composite
  - Uniform distribution
  - Independence
- Unpredictability, e.g. protocols relay on unpredictable values so attacker cannot generate fake/replay messages

### Random vs Pseudo-random

## Encrypt for

Authenticatio

Public Ke

Key Managemer

Random Numbers

Summar

## Pseudo-random Number Generators (PRNG)

- ► Algorithms used to generate random numbers
- Algorithms are deterministic, therefore numbers produced are not statistically unpredictable or independent
- However good algorithms produce sequences of number that pass many randomness tests

### True Random Number Generators

- ▶ Use non-deterministic source to produce randomness
  - Measure ionising radiation events, leaky capacitors, thermal noise from resistor, disk reads of hard disks, . . .
- Require hardware for measurements

Summary

## Common Principles used in Security

- Experience: Algorithms that have been used over a long period are less likely to have security flaws than newer algorithms.
- Performance: Symmetric key algorithms are significantly faster than public key algorithms.
- Performance: The time to complete a cryptographic operation is linearly proportional with the input data size.
- ► *Key Distribution*: Keys should be distributed using automatic means.
- ► Key Re-use: The more times a key is used, the greater the chance of an attacker discovering that key.
- ► *Multi-layer Security*: Using multiple overlapping security mechanisms can increase the security of a system.
